# Full SVD

#### Definition

(Full SVD) Any  $m \times n$  real matrix A, with  $m \ge n$ , can be factorized into

$$A = U \begin{pmatrix} \Sigma \\ 0 \end{pmatrix} V^{T},$$

where  $U \in \mathbb{R}^{m \times m}$  and  $V \in \mathbb{R}^{n \times n}$  are orthogonal, and  $\Sigma \in \mathbb{R}^{n \times n}$  is diagonal with

$$\Sigma = \operatorname{diag}(\sigma_1, \sigma_2, \ldots, \sigma_n), \ \sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_n \geq 0.$$

JEN-MEI CHANG (CSU, LONG BEACH)

GEOMETRIC DATA ANALYSIS

OCTOBER 28, 2009 5 / 56

# Thin SVD

#### Definition

(**Thin SVD**) With the partitioning  $U = (U_1, U_2)$ , where  $U_1 \in \mathbb{R}^{m \times n}$ , we get the *thin SVD* 

$$A = U_1 \Sigma V^T,$$

#### Structural Illustration:

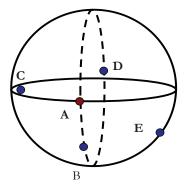

$$A = U_1 \Sigma V^T = (u_1 \ u_2 \ \cdots \ u_n) \begin{pmatrix} \sigma_1 & & \\ & \sigma_2 & \\ & & \ddots & \\ & & & \sigma_n \end{pmatrix} \begin{pmatrix} v_1^T \\ v_2^T \\ \vdots \\ v_n^T \end{pmatrix} = \sum_{i=1}^n \sigma_i u_i v_i^T.$$

# Approximation theorem

If we know the correct rank of A, e.g., by inspecting the singular values, then we can **remove the noise and compress the data** by approximating A by a matrix of the correct rank. One way to do this is to truncate the singular value expansion:

#### Theorem

lf

$$\boldsymbol{A}_{k} = \sum_{i=1}^{k} \sigma_{i} \boldsymbol{u}_{i} \boldsymbol{v}_{i}^{T} \quad (1 \leq k \leq r)$$

then

$$A_k = \min_{\operatorname{rank}(B)=k} \|A - B\|_2 \quad \text{and} \quad A_k = \min_{\operatorname{rank}(B)=k} \|A - B\|_F.$$

#### IMAGE COMPRESSION

# An example

The error term of rank *k* approximation is given by the (k + 1)<sup>th</sup> singular value  $\sigma_{k+1}$ .

(a) full rank (rank 480)

(b) rank 10, rel. err. = 0.0551

(c) rank 50, rel. err. = 0.0305 (d) rank 170, rel. err. = 0.0126

# General classification paradigm

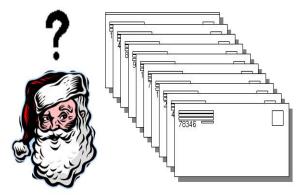

JEN-MEI CHANG (CSU, LONG BEACH)

GEOMETRIC DATA ANALYSIS

**OCTOBER 28, 2009** 12/56

#### Problem definition

Santa thought to himself, "only if these mails can go to the right place according to their zip code".

# Handwritten digit classification

**Problem.** (Human) handwritten digits are sometimes very hard to recognize, even by human operators.

**Importance.** Accurate identification of the digits ensures a reliable delivery system.

**Beneficiaries.** Postal services (mail sorting), seaports (cargo registration), etc.

Even Santa Clause can benefit from an efficient digit classification algorithm.

JEN-MEI CHANG (CSU, LONG BEACH)

GEOMETRIC DATA ANALYSIS

#### How do we tell whether a new digit is a 4 or a 9?

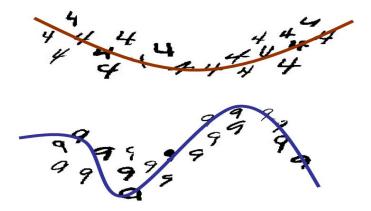

7 99 99 99 99 99 9 9 9 9 9 9 9 9 9 9

GEOMETRIC DATA ANALYSIS

OCTOBER 28, 2009 25 / 56

< 🗇 > < 🖻 > <

# **Empirical fact**

Images of a single person seen under variations of illumination appear to be more difficult to recognize than images of different people [Zhao et al., 2003].

Can you tell who this is?

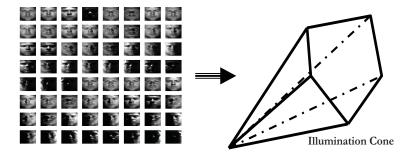

Subject 1

OCTOBER 28, 2009 26 / 56

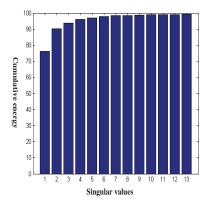

#### Geometric facts - 1

The set of *m*-pixel monochrome images of an object seen under general lighting conditions forms a convex polyhedral cone (illumination cone) in  $\mathbb{R}^m$  [Belhumeur & Kriegman, 1998].

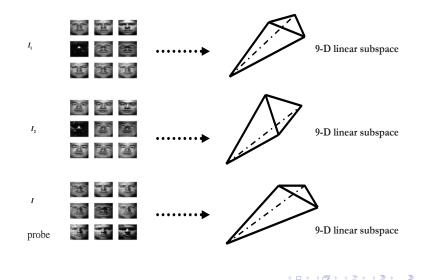

#### Geometric facts - 2

The illumination cone can be approximated by a 9-dimensional linear subspace [Basri & Jacobs, 2003], i.e., the illumination cone is low-dimensional and linear.

#### Set-up

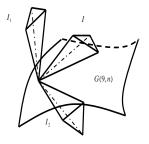

JEN-MEI CHANG (CSU, LONG BEACH)

GEOMETRIC DATA ANALYSIS

OCTOBER 28, 2009 29 / 56

# Definition of G(k, n)

These illumination cones are all elements of a parameter space called the **Grassmannian (Grassmann manifold)**, G(9, n), where *n* in the ambient dimension.

#### Definition

The *Grassmannian* G(k,n) or the *Grassmann manifold* is the set of *k*-dimensional subspaces in an *n*-dimensional vector space  $K^n$  for some field K, i.e.,

$$G(k,n) = \{ W \subset K^n \mid \dim(W) = k \}.$$

# Principal angles [Björck & Golub, 1973]

It turns out that any attempt to construct an unitarily invariant metric on G(k, n) yields something that can be expressed in terms of the **principal angles** [Stewart & Sun, 1990].

#### Definition

If X and Y are two vector subspaces of  $\mathbb{R}^m$ , then the principal angles  $\theta_k \in [0, \frac{\pi}{2}]$ ,  $1 \le k \le q$  between X and Y are defined recursively by

$$\cos(\theta_k) = \max_{u \in X} \max_{v \in Y} u^T v = u_k^T v_k$$

subject to ||u|| = ||v|| = 1,  $u^T u_i = 0$  and  $v^T v_i = 0$  for i = 1 : k - 1 and  $q = \min \{\dim(X), \dim(Y)\} \ge 1$ .

# Grassmannian distances [Edelman et al., 1999]

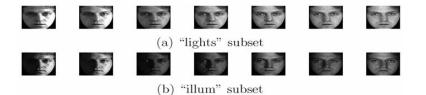

These are the distance functions we will use to compare points on the Grassmann manifold.

| Metric Name                 | Mathematical Expression  |
|-----------------------------|--|
| Fubini-Study                | $d_{FS}(\mathcal{X}, \mathcal{Y}) = \cos^{-1} \left( \prod_{i=1}^{k} \cos \theta_{i} \right)$ $d_{c2}(\mathcal{X}, \mathcal{Y}) = \left\  2 \sin \frac{1}{2} \theta \right\ _{F}$ $d_{cF}(\mathcal{X}, \mathcal{Y}) = \left\  2 \sin \frac{1}{2} \theta \right\ _{2}$ $d_{g}(\mathcal{X}, \mathcal{Y}) = \  \theta \ _{2}$ |
| Chordal 2-norm              | $d_{c2}(\mathcal{X},\mathcal{Y}) = \left\  2\sin\frac{1}{2}\theta \right\ _{F}$  |
| Chordal F-norm              | $d_{cF}(\mathcal{X},\mathcal{Y}) = \left\  2\sin\frac{1}{2}\theta \right\ _{2}$  |
| Geodesic (Arc Length)       | $d_{g}(\mathcal{X},\mathcal{Y}) = \ \ddot{\theta}\ _{2}$   |
| Chordal (Projection F-norm) | $d_{c}(\mathcal{X},\mathcal{Y}) = \ \sin\theta\ _{2}$  |
| Projection 2-norm           | $egin{array}{l} d_{ m p2}\left(\mathcal{X},\mathcal{Y} ight) = \left\ \sin	heta ight\ _{\infty} \end{array}$   |

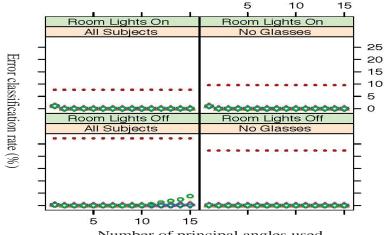

#### Empirical result - database

Since we are only concerned with the lighting variations, we fix the frontal pose, neutral expression and select the "illum" and "lights" subsets of CMU-PIE (68 subjects, 13 poses, 43 lightings, 4 expressions) [Sim et al., 2003] for experiments.

- lights: 21 illumination conditions with background lights on.
- illum: 21 illumination conditions with background lights off.

## **Empirical results**

#### Robustness

If the data set is perfectly separable with the Grassmann method when using this kind of image [Chang et al., 2006a]:

The data set is still perfectly separable with the Grassmann method when using this kind of image [Chang et al., 2007bc]:

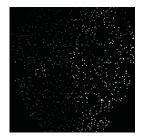

GEOMETRIC DATA ANALYSIS

#### Robustness

If the data set is perfectly separable with the Grassmann method when using this kind of image [Chang et al., 2006a]:

Bankruptcy prediction is the art of predicting bankruptcy and various measures of financial distress of public firms. It is a vast area of finance and accounting research. The importance of the area is due in part to the relevance for creditors and investors in evaluating the likelihood that a firm may go bankrupt<sup>1</sup>.

- If we form a feature vector for each firm.
- The problem becomes a two-class classification problem.

# **Two-Class LDA**

$$m_1 = \frac{1}{n_1} \sum_{x \in D_1} w^T x, \quad m_2 = \frac{1}{n_2} \sum_{y \in D_2} w^T y$$

Look for a projection *w* that

- maximizes (inter-class) distance in the projected space,
- and minimizes the (intra-class) distances in the projected space.

JEN-MEI CHANG (CSU, LONG BEACH)

GEOMETRIC DATA ANALYSIS

### **Two-Class LDA**

Namely, we desire a  $w^*$  such that

$$w^* = \arg\max_{w} \frac{(m_1 - m_2)^2}{S_1 + S_2},$$
  
where  $S_1 = \sum_{x \in D_1} (w^T x - m_1)^2$  and  $S_2 = \sum_{y \in D_2} (w^T y - m_2)^2.$   
Alternatively, (with scatter matrices)  
 $w^* = \arg\max_{w} \frac{w^T S_B w}{w^T S_W w},$  (1)

with  $S_W = \sum_{i=1}^{2} \sum_{x \in D_i} (x - \mathbf{m}_i) (x - \mathbf{m}_i)^T$ ,  $S_B = (\mathbf{m}_2 - \mathbf{m}_1) (\mathbf{m}_2 - \mathbf{m}_1)^T$ .

## **Two-Class LDA**

Namely, we desire a  $w^*$  such that

$$w^* = rgmax_w rac{(m_1 - m_2)^2}{S_1 + S_2},$$

where 
$$S_1 = \sum_{x \in D_1} (w^T x - m_1)^2$$
 and  $S_2 = \sum_{y \in D_2} (w^T y - m_2)^2$ .  
Alternatively (with scatter matrices)

Allematively, (with scatter matrices)

$$w^* = \arg\max_{w} \frac{w^T S_B w}{w^T S_W w},\tag{1}$$

with 
$$S_W = \sum_{i=1}^2 \sum_{x \in D_i} (x - \mathbf{m}_i) (x - \mathbf{m}_i)^T$$
,  $S_B = (\mathbf{m}_2 - \mathbf{m}_1) (\mathbf{m}_2 - \mathbf{m}_1)^T$ .

# The criterion in Equation (1) is commonly known as the generalized Rayleigh quotient, whose solution can be found via the generalized eigenvalue problem

$$S_B w = \lambda S_W w.$$

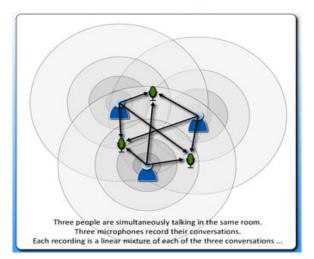

LDA for multi-class follows similarly.

The criterion in Equation (1) is commonly known as the generalized Rayleigh quotient, whose solution can be found via the generalized eigenvalue problem

$$S_B w = \lambda S_W w.$$

LDA for multi-class follows similarly.

### **Cocktail Party Problem**

ヘロト ヘ戸ト ヘヨト ヘヨト

# KL procedure for noisy data

• Decompose observed data into its *noise* and *signal* components:

$$\mathbf{x}^{(\mu)} = \mathbf{s}^{(\mu)} + \mathbf{n}^{(\mu)},$$

or, in terms of data matrices,

$$X = S + N$$
. ( $S =$ signal,  $N =$ noise)

 The optimal first basis vector, φ, is taken as a superposition of the data, i.e.,

$$\phi = \psi_1 \mathbf{x}^{(1)} + \dots + \psi_P \mathbf{x}^{(P)} = X \psi.$$

• May decompose  $\phi$  into signal and noise components

$$\phi = \phi_{\mathbf{n}} + \phi_{\mathbf{s}},$$

where  $\phi_{\mathbf{s}} = \mathbf{S}\psi$  and  $\phi_{\mathbf{n}} = \mathbf{N}\psi$ .

#### **MNF/BBS**

 The basis vector φ is said to have maximum noise fraction (MNF) if the ratio

$$D(\phi) = \frac{\phi_{\mathbf{n}}^T \phi_{\mathbf{n}}}{\phi^T \phi}$$

is a maximum.

• A steepest descent method yields the *symmetric definite* generalized eigenproblem

$$N^T N \psi = \mu^2 X^T X \psi.$$

This problem may be solved without actually forming the product matrices  $N^T N$  and  $X^T X$ , using the generalized SVD (gsvd).

 Note that the same orthonormal basis vector φ optimizes the signal-to-noise ratio. And this technique is called Blind Source Separation (BSS).

JEN-MEI CHANG (CSU, LONG BEACH)

# **Convolution - sharpening**

Filtering with high-pass filters.

$$w(x, y) \star f(x, y) = \sum_{s=-a}^{a} \sum_{t=-b}^{b} w(s, t) f(x - s, y - t)$$
$$= \sum_{s=-a}^{a} \sum_{t=-b}^{b} f(s, t) w(x - s, y - t)$$
