Samantha Godfrey

Peter Steinhoff

MATH 579: Mathematical Modeling

Professor Chang

March 22, 2011

# Topics of Research

- The connections between maternal conditions and placenta weight
- Implementation of Statistical Analysis and Principal Component Analysis
- Different combinatorial indicators of placental growth

# Maternal Variables

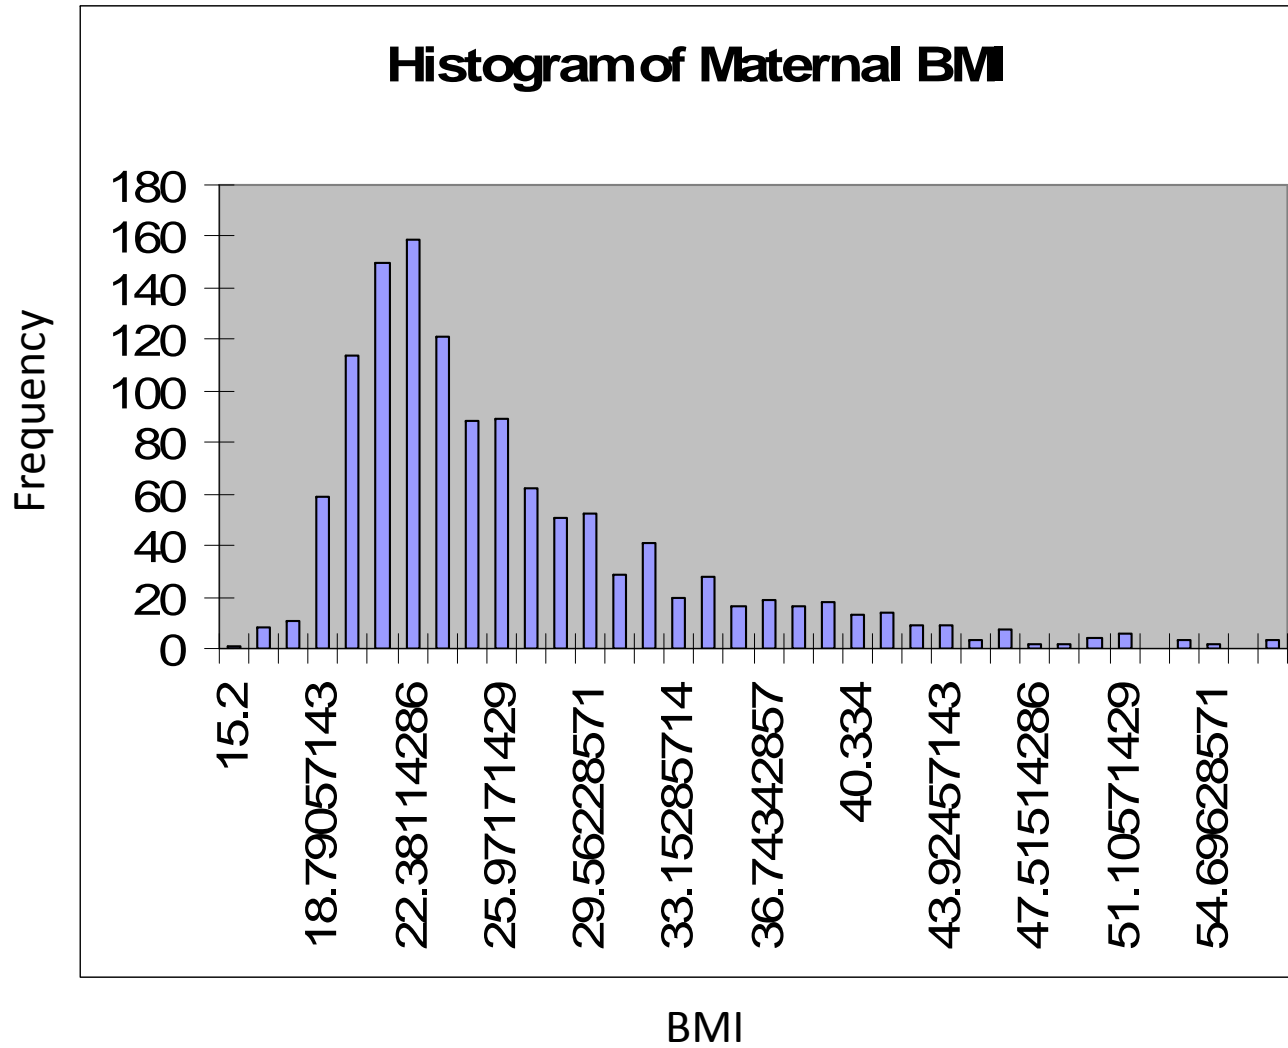

- Maternal Pre-Pregnancy BMI
- Maternal Age
- Mother's Ethnicity
- Gestational Diabetes

# What is Placental Ratio?

$$\text{Placental Ratio} = \frac{\text{Placental Weight}}{\text{Birth Weight}}$$

# What is the average Maternal BMI?

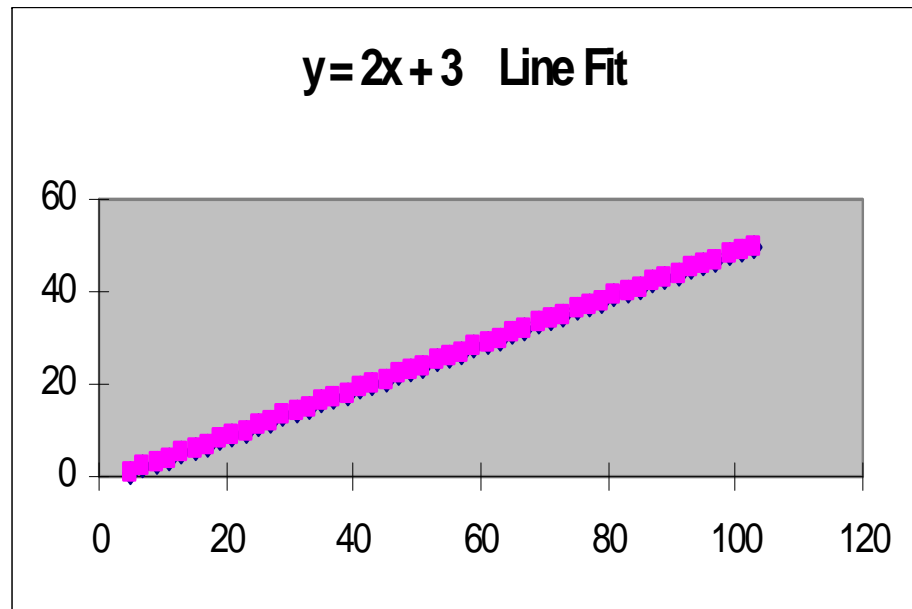

# $R^2$ and F significance values

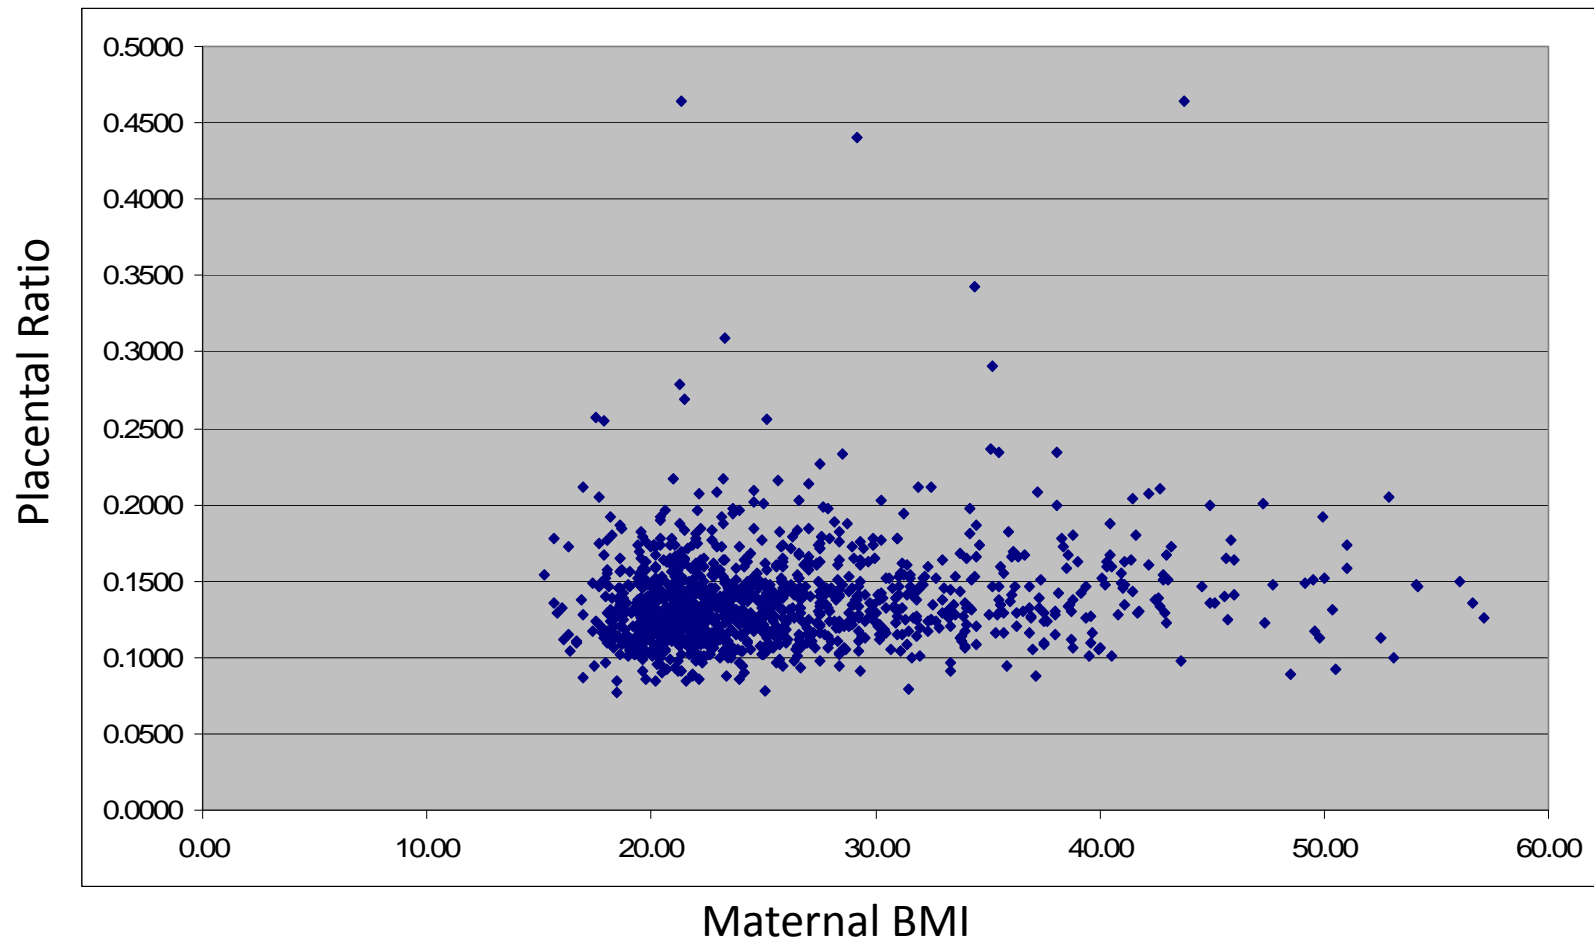

$R^2$  value= 1

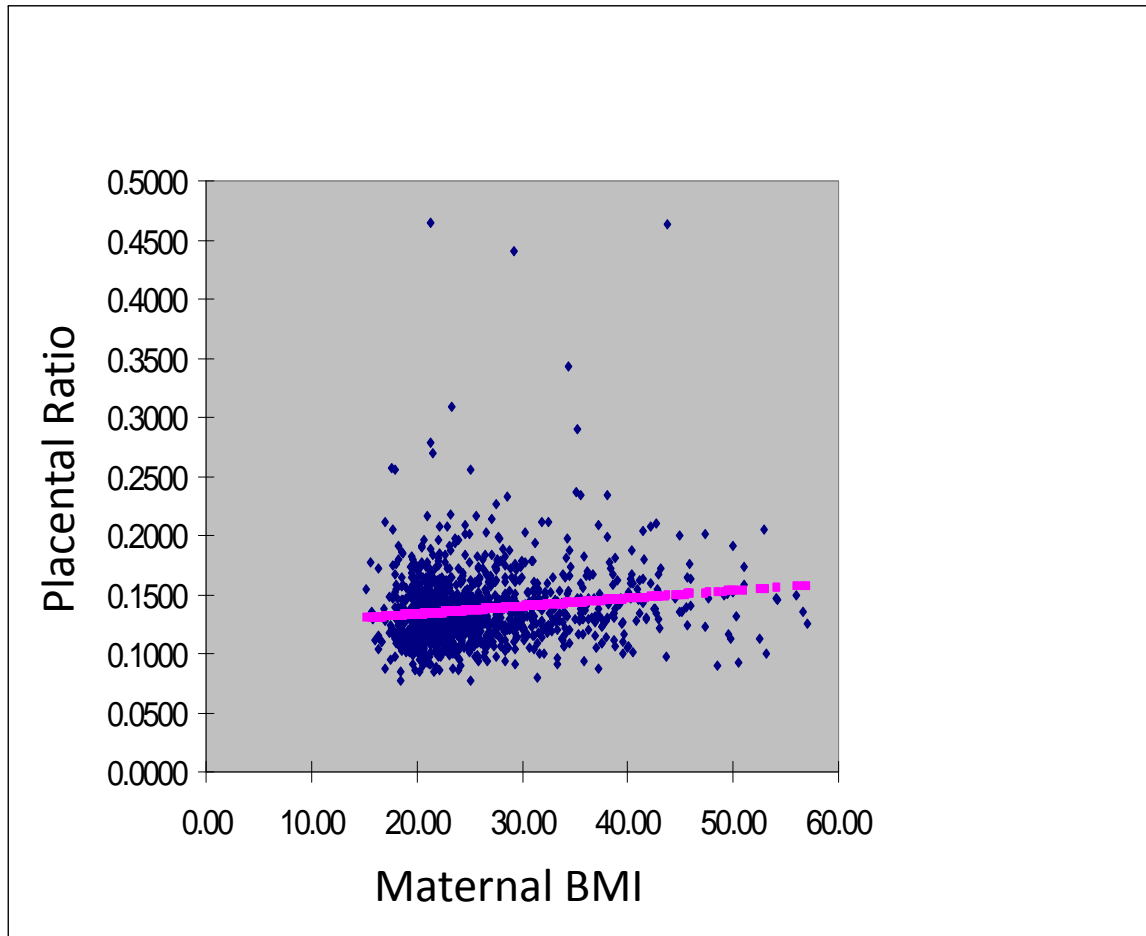

F significance = 0

# Maternal BMI vs. Placental Ratio

# Maternal BMI vs. Placental Ratio Line Fit Plot

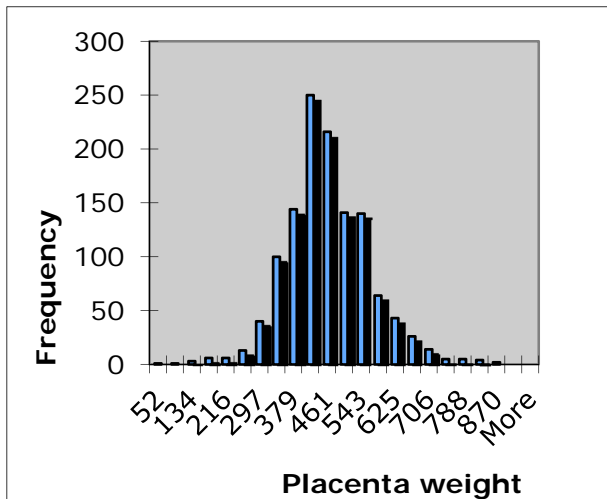

R<sup>2</sup> value= .020921

F significance =  
3.54E-07

Conclusion: A linear correlation exists between Maternal BMI and Placental Ratio.

# Maternal Age and Placenta Weight

## Statistical results

$R^2$  value: 0.000192

F-stat P value: 0.628717

## Conclusion:

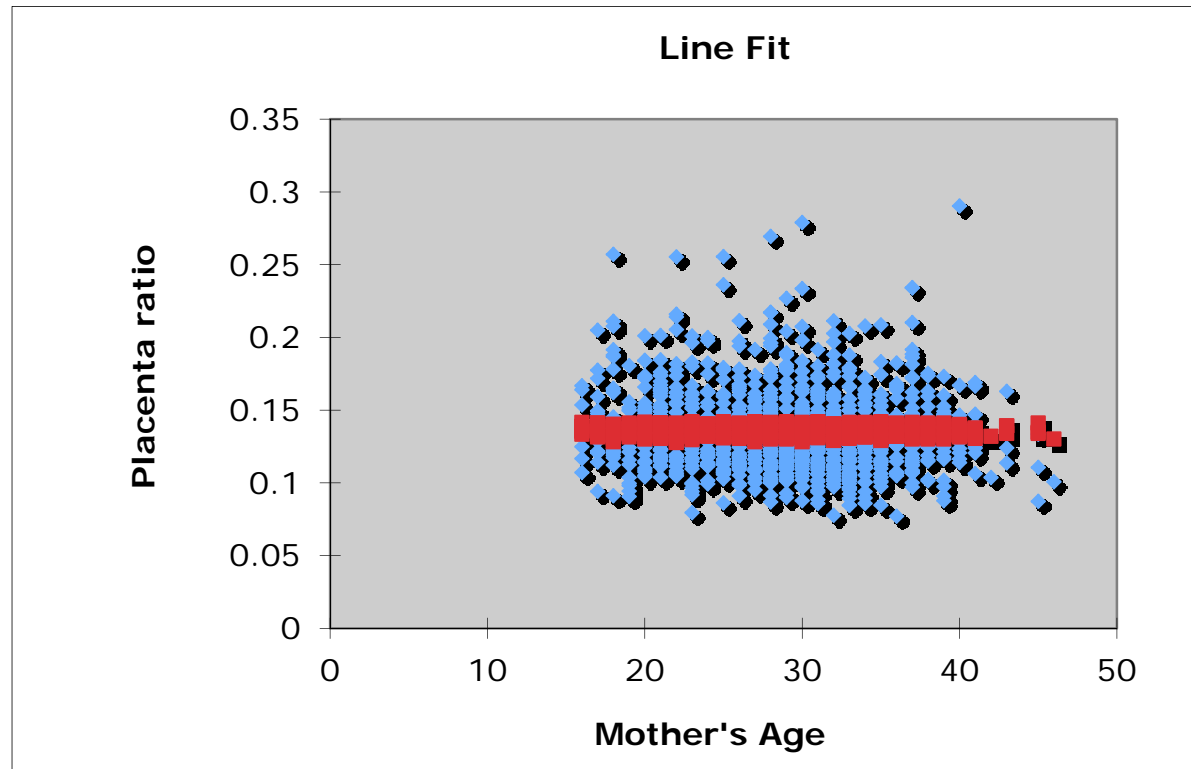

There is no correlation between maternal age and placenta weight

# Maternal Age and Placenta Ratio

## Statistical Results

R<sup>2</sup> value: 0.01

F-stat P-value: 0.0005

## Conclusions

- There is a statistically significant correlation between maternal age and placenta ratio. However, the relationship is so weak that a linear fit is basically useless.

# Mother's Ethnicity

- Highest average placenta weight with white mothers (449.49±101.94)
- Lowest average placenta weight with African American mothers (418.81±115.79)

# Mother's Ethnicity

- Highest placental ratio with African American mothers (.1434±.0331)
- African American babies in this study had the lowest average birth weight compared to their placenta weight
- Average placental ratio ranged from 13.3% to 14.4%

# Gestational Diabetes

- Gestational diabetes is a type of diabetes that is found for the first time when a woman is pregnant. This diabetes means that the blood sugar level is too high.
- In our data we have 1182 women without gestational diabetes and 47 women with gestational diabetes.
- The mean placenta weight of the women with gestational diabetes is 460 while the mean placenta weight of the non-gestational diabetes women is 438.

# Gestational Diabetes

- In the non-gestational diabetes group there are 565 women below the mean placenta weight and 617 above it.
- In the gestational diabetes group there are 28 women below the mean placenta weight and 19 above it.

# Principal Component Analysis

- PCA is a procedure that uses an *orthogonal transformation* to convert a set of possibly correlated variables into a set of uncorrelated variables
- By testing different variable combinations, we wish to observe if data can be “separable”, suggesting a pattern.

# Principal Component Analysis Example

Maternal Age, Pre-Pregnancy BMI, and Placental Weight as chosen variables and color-coded by Ethnicity

# Another Example

Maternal Age, Pre-Pregnancy BMI, and Placental Ratio as chosen variables and color-coded by Ethnicity

# Further Research

1. Grouping and classification within the Principle Component subspace
  - K –mean method
  - Nearest Neighbor Method
2. Further Statistical Investigations
  - Logistical Regression
3. Another Direction Entirely
  - Suggestions?
